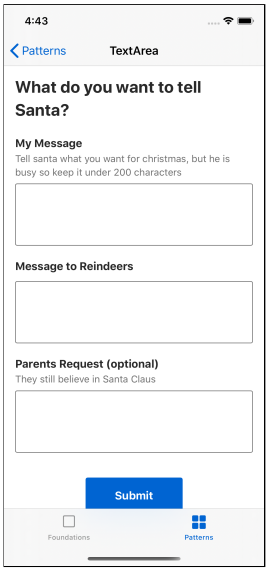
iOS Developer Guide - Text Area

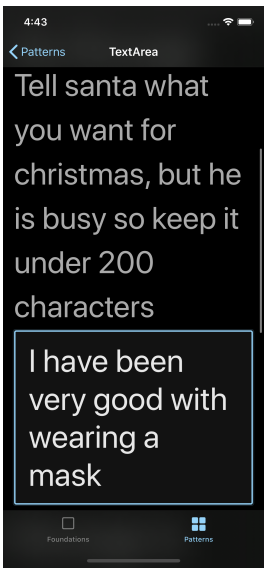
Created by Peggy Liu, last modified on 11 Jan 2021

Text Area can be used to gather text input longer than a single line (e.g. user feedback).

For single line input use Text Field instead.

Find in the catalogue app: Patterns → TextArea





Light normal vs Dark large accessibility text

Sample implementation in catalogue app

https://git02.ae.sda.corp.telstra.com/projects/ABLE/repos/able-ios-catalogue-app/browse/AbleCatalogue/Application/Application/Pattern/SwitchRow

Quick Code Reference Guide:

Creating a Text Area

```
//initialise:
var textArea = TextArea()

//Set properties
switchRow.labelText = "toggle this on if you dare"
switchRow.isOn = false //default is false

//this is handler for textfieldDidEndEditingHandler
      textArea.validationHandler = handler
//this is handler for textfieldChanged
     textArea.onEditingValidationHandler = inlineHandler
```

Using a TextArea

```
//create validation handlers as needed

//This runs after validation in textAreaDidEndEditing
// validationResult checks that the textArea is not empty if required
 let validationHandler: ValidationHandler = { validationResult in
                self.validationResults[0] = validationResult
                switch validationResult {
                case .success(let textInArea):
                    print("Do something with the text: \(textInArea)")
                case .failure: break
                }
                self.refreshCell()
            }
```

```
//This runs after validation in textAreaChanged
let inlineValidationHandler: ValidationHandler = { validationResult in
                self.refreshCell()
            }

//sample submit button logic:
cell.submitAction = {
            //check validations and submit whatever is needed
            //if error , focus on first field with error
            for index in [1, 2, 3] {

                if let areaCell = tableView.cellForRow(at: IndexPath(row: index, section: 0)) as? TextAreaViewCell {
                    areaCell.textArea.validateValueUpdateState(onEditing: false)
                    if self.validationResults[index-1] == .failure(.empty) {
                        _ = areaCell.textArea.becomeFirstResponder()
                        break
                    }
                    self.refreshCell()
                }
            }
        }
//You can set the validation messages
textArea.showFieldValidationMessage(for: validationResult, onEditing: false)
```
